

## Supporting Information Files

**Appendix S1** Definitions of the metrics used in this study to describe network structure.

### Network level parameters:

- (1) *Species richness*. Total number of plants and animals in the bipartite network.
- (2) *Connectance*. Realized proportion of possible links: sum of links divided by number of cells in the matrix (the latter being the product between the number of higher trophic level species –animals, in our case- and the number of lower trophic level species –plants, in our case).
- (3) *Interaction asymmetry* (or *interaction strength asymmetry*). Difference between the interaction strength (i.e. the relative frequency) of each animal species  $i$  on each plant species  $j$  and its reverse from the plant perspective, standardized by the sum of interaction strength values of species  $i$  on  $j$  and of species  $j$  on  $i$  (Bascompte *et al.* 2006; extended by Blüthgen 2010). Values vary between -1 and 1, where positive values indicate a high dependence of animal on plant species and negative values indicate the opposite. Given that this variable, by its mathematical definition, is closely associated with web asymmetry, this correlation is accounted with null models (see further details in Blüthgen 2010). Thus, for each network in the data set, we computed 1000 randomized interaction matrices simulated with the Patefield algorithm, which randomly redistributes interaction events among all cells of the matrix while holding the number of interaction events per species constant. Thus, web asymmetries were held constant in all

simulated networks, while interactions were reallocated between pairs of species according to species interaction frequencies. The difference between observed asymmetries of interaction strength and the mean asymmetry of interaction strength across the 1000 simulations gives the null-model-corrected asymmetry of interaction strength.

- (4) *Interaction evenness (IE)*, a measure of the uniformity of interactions between species in a network, based on Shannon's evenness (Tylianakis *et al.* 2007). An uneven network has a high skewness in the distribution of interaction weights. It ranges from 0 (completely uneven) to 1 (completely uniform).
- (5) *Network specialization  $H_2'$*  (Blüthgen *et al.* 2006). Measure of the level of network selectiveness, is also derived from Shannon entropy and is related to weighted specialization ( $d'$ ) across all species. It ranges between 0 (opportunistic, high niche overlap) and 1 (selective, high niche differentiation).
- (6) *Weighted NODF* (WNODF; Weighted Nestedness based on Overlap and Decreasing Fill; Almeida-Neto & Ulrich 2011), a measure of the degree of nestedness for quantitative data. Networks are nested if those species with fewer interactions are preferentially associated with a subset of species that interact with the most connected ones. It ranges from 0 (not nested network) to 100 (highly nested network). The significance of WNODF was tested by comparing it with that obtained from 1000 randomized networks constrained by the total abundances of each row and column as the empirical one; we used the null model  $rc$ , which assigns individuals to matrix cells proportional

to observed row and column abundance totals until, for each row and column, total abundances are reached.

(7) **Modularity ( $M$ )**, refers to the existence of subsets (modules) of more closely interacting species with relatively few or no interactions to other subsets (Guimerà *et al.* 2010). It was obtained with the software MODULAR (Marquitti *et al.* 2014).

#### **Species level parameters:**

(8) **Species specialization for plants ( $d_p$ ) and animals ( $d_a$ )** (Blüthgen *et al.* 2006) gives levels of specialization of each species, accounting for the available resources provided by the interaction partners (calculated as marginal totals in the matrix). This index increases with the deviation from random selection of the available interaction partners based on their abundance. Thus, a pollinator species, for example, that visits flowering plant species proportionally to their availability in the community is considered generalized, while a species that visits rare plants disproportionately is considered specialized. It is actually an index of selectivity, thus we could call the ‘generalized’ species as ‘opportunistic’ and the ‘specialized’ species as ‘selective’. Note that a particular species can be opportunistic in one community but selective in another one, depending on the abundance of its partners.

(9) **Species strength.** The strength of an animal species ( $st'_a$ ) is defined as the sum of dependencies of the plants relying on the particular pollinator, whereas the strength of a plant ( $st'_p$ ) is the sum of dependencies of the pollinators relying on the particular plant species (Bascompte *et al.* 2006).

We calculated the dependence of a pollinator species on a particular plant species by dividing the number of visits of that pollinator to that plant by the total number of pollinator visits that plant receives. Conversely, the dependence of a plant species on a particular pollinator species is obtained by dividing the number of times the pollinator visited the plant by the total number of visits of that pollinator species to plants in the community.

**Table S1** Complete list of flowering species observed in this study, including origin, overall number of observed visits per plant species and estimated flower abundance (calculated by multiplying the mean number of flowers on two individuals per transect by the total number of individuals counted along the transects). The eight plant species that have not received any recorded visit during the censuses are marked with an asterisk.

Family	Species	Origin	Total observed number of visits	Total estimated flower abundance
Acanthaceae	<i>Blechum pyramidatum</i>	Native	7	939
Acanthaceae	<i>Justicia galapagana</i>	Endemic	11	246
Amaranthaceae	<i>Alternanthera echinocephala</i>	Native	93	162387

Insecta	Lepidoptera	Lantanophaga pusilliadactyla	Introduced	1
Insecta	Lepidoptera	Lepidoptera sp. 1		9
Insecta	Lepidoptera	Leptotes parrhasioides	Endemic	273
Insecta	Lepidoptera	Leucania cooperi	Endemic	2
Insecta	Lepidoptera	Loxomorpha cf. cambogialis	Native	1
Insecta	Lepidoptera	Manduca rustica	Endemic	9
Insecta	Lepidoptera	Melipotis harrisoni	Endemic	3
Insecta	Lepidoptera	Melipotis indomita	Native	3
Insecta	Lepidoptera	Neohelvibotis sp. 1	Endemic	8
Insecta	Lepidoptera	Neohelvibotis sp. 2		1
Insecta	Lepidoptera	Neohelvibotis sp. 3		3
Insecta	Lepidoptera	Omiodes indicata	Introduced	3
Insecta	Lepidoptera	Ommatochila mundala	Native	2
Insecta	Lepidoptera	Oxydia lignata	Endemic	1
Insecta	Lepidoptera	Paectes arcigera	Introduced	1
Insecta	Lepidoptera	Perigonia lusca	Native	1
Insecta	Lepidoptera	Phoebis sennae	Native	335
Insecta	Lepidoptera	Psara chathamalis	Endemic	4
Insecta	Lepidoptera	Pseudoplusia includens	Native	486
Insecta	Lepidoptera	Pterophoridae		4
Insecta	Lepidoptera	Pterophoridae sp. 1		38
Insecta	Lepidoptera	Pterophoridae sp. 2		9
Insecta	Lepidoptera	Pyralidae sp. 1		6
Insecta	Lepidoptera	Pyralidae sp.2		7
Insecta	Lepidoptera	Pyrausta panopealis	Introduced	57
Insecta	Lepidoptera	Pyrausta sp.		3
Insecta	Lepidoptera	Spoladea recurvalis	Introduced	145
Insecta	Lepidoptera	Spragueia margana	Introduced	9
Insecta	Lepidoptera	Spragueia sp.1		2
Insecta	Lepidoptera	Syngamia florella	Introduced	155
Insecta	Lepidoptera	Tineidae sp.1		1
Insecta	Lepidoptera	Tota galdinella	Endemic	2
Insecta	Lepidoptera	Urbanus dorantes	Endemic	696
Insecta	Lepidoptera	Utetheisa ornatrix	Native	4

Insecta	Lepidoptera	<i>Zale obsita</i>	Native	5
Insecta	Odonata	<i>Ischnura hastatum</i>	Native	1
Insecta	Orthoptera	Acrididae		2
Insecta	Orthoptera	Acrididae sp.2		1
Insecta	Orthoptera	<i>Anaulocomera darwini</i>	Endemic	10
Insecta	Orthoptera	<i>Gryllus</i> sp.		4
Insecta	Orthoptera	<i>Jarmilaxiphia ecuadorica</i>	Introduced	4
Insecta	Thysanoptera	<i>Thysanoptera</i> sp. 1		1
Reptilia	Squamata	<i>Microlophus bivittatus</i>	Endemic	1

**Figure S1.** Illustration of the entire pollination network, comprising data from the two islands (Santa Cruz and San Cristóbal), the three habitats (arid, transition and humid zones) and the two seasons (hot and cold). Data from 2010 and 2011 are also pooled. Plant species are depicted at the bottom of the network whereas pollinators are at the superior part of it. Alien (A) plants and their links are represented in red colour to illustrate the magnitude of the interactions in which they are involved, whereas endemic (Nze) and non-endemic natives (Nt) are represented in black and gray colour, respectively.

**Figure S2.** Mean ( $\pm$  1 S.E.) of network metrics showing differences between the two seasons across habitats for each study island in the hot season of 2011. Data on interaction evenness (IE) are shown for comparison with data from Figure 2 (2010 data), although differences across habitats were not significant this year. For each island, bars with the same letters indicate no differences across habitats ( $P > 0.05$ ).

**Figure S3.** Mean ( $\pm$  1 S.D.) of the species-level parameters analysed in this study, for both pollinators and plants, showing differences among species from different habitats for the two islands, and the two seasons of 2010. Bars with the same letters on each graph indicate no differences across habitats ( $P > 0.05$ ).
